reproduces elsewhere
holds when variants are correlated
holds when one locus is dropped
holds after correcting for many tests
supported by external data
the test is well calibrated
Comparing ranked lists cannot tell shared from separate causes
How often it fires by chance depends on the list length chosen
A direct test of difference performs better
Enrolment flags alone place 93% of participants correctly
The reported accuracy comes from study-design columns
Nonlinear models do no better than adding up risk alleles
Higher common-variant burden means earlier onset
...by 1.97 years per standard deviation specifically
Across 86 loci, risk alleles also bring onset forward
Early and late onset differ variant by variant
Lysosomal loci carry extra signal on onset
No pathway acts on onset beyond its effect on risk
Raised GALC activity holds up on an independent test
GALC and LRRC37A2 act on risk rather than on onset
